

Integration Hub PRD Overview

May 2026

Problem

We're building integrations. Is that enough?

Key Pain Points:

- **Discovery gap:** No central catalog showing supported integrations
- **Fragmented setup:** Configuration requires documentation hunting; cloud/API integrations need engineering involvement
- **Zero operational visibility:** No way to confirm integrations are working or diagnose failures
- **Hidden value:** Difficult to understand how use the data integrations provide.

Who:

- **Platform Engineers:** Manage collectors, standardize integration configurations across environments
- **Site Reliability Engineer (SRE):** Maintain observability for production services, respond to incidents

Solution Goals

1. **Reduce time-to-value:** Users can discover, install, and validate integrations in minutes, not hours
2. **Enable self-service troubleshooting:** Integration status and health checks provide actionable diagnostics
3. **Streamline value:** Automated installation of OOTB assets during Datadog migrations

Integration Hub Concept

XCOR Integration Hub Delivers Enterprise-Grade Integration Experience in Minutes, Not Days

Self-service integration catalog with one-click installation, automated health monitoring, and pre-built dashboards eliminates configuration guesswork.

Example user flow - collector integration

Flow 1: Discover and Install a Collector Integration (New Integration)

1. User navigates to Integration Hub
2. Searches or browses for "Redis" integration
3. Clicks Redis tile (status: "Available")
4. Reviews integration details: telemetry catalog, OOTB assets, configuration requirements
5. Copies XCOR Collector configuration snippet from UI
6. Pastes config into collector YAML and restarts collector
7. Returns to Integration Hub, clicks "Install"
8. OOTB dashboards appear in user's dashboard list

Example user flow - collector integration

Flow 4: Configure a Server-Side Cloud/API Integration

1. Search for “Cloudflare” in the integration hub
2. User clicks Cloudflare integration tile (status: "Available")
3. User sees the integration details tile (configuration instructions, OOTB asset list)
4. Users clicks "Add new..."
5. UI shows required configuration: API token, zone IDs, polling interval
6. User enters credentials, clicks "Save"
7. System validates credential token or shows errors if credentials are not valid
8. Status changes to "Installed", OOTB dashboards are created (if they don't already exist)
9. User exports config as Terraform for version control (redacting any token or secrets)
